

## Birthday bounds

---

### Classical birthday bound.

Let  $y_1, \dots, y_q$  be uniformly and independently drawn from a size- $N$  set. Then

$$1 - e^{q(q-1)/2N} \leq \Pr[\exists i \neq j, y_i = y_j] \leq \frac{q(q-1)}{2N}.$$

If furthermore  $q \leq \sqrt{2N}$ , the lower bound is  $\geq \frac{q(q-1)}{4N}$ .

*Proof of the upper bound.* The probability that two independent elements drawn from a size- $N$  set are equal is at most  $1/N$ . Therefore, using the union bound,  $\Pr[\exists i \neq j, y_i = y_j] \leq \sum_{i \neq j} 1/N = q(q-1)/2N$ .  $\square$

*Proof of the lower bound.* Let  $N_i$  be the event “there is no collision amongst  $y_1, \dots, y_i$ .” We want to lower bound  $\Pr[\neg N_q]$ , that is to upper bound  $\Pr[N_q]$ . Using the law of total probability,  $\Pr[N_q] = \Pr[N_q|N_{q-1}] \Pr[N_{q-1}] + \Pr[N_q|\neg N_{q-1}] \Pr[\neg N_{q-1}]$ . But  $\Pr[N_q|N_{q-1}] = 0$ . Therefore,  $\Pr[N_q] = \Pr[N_q|\neg N_{q-1}] \Pr[\neg N_{q-1}]$ . Hence, by induction

$$\Pr[N_q] = \Pr[N_1] \cdot \Pr[N_2|N_1] \cdots \Pr[N_q|N_{q-1}].$$

Now,  $\Pr[N_1] = 1$  (since there cannot be a collision between one element). And for  $i > 1$ ,  $\Pr[N_i|N_{i-1}]$  is the probability that  $y_i$  collides with a  $y_j$ ,  $j < i$ , assuming they are all different. Since  $y_i$  is drawn independently of the previous  $y_j$ 's,  $\Pr[N_i|N_{i-1}] = 1 - (i-1)/N$ .

Together, we obtain that  $\Pr[N_q] = \prod_{i=1}^{q-1} (1 - i/N)$ . Since  $1 + x \leq e^x$  for all  $x$ ,

$$\Pr[N_q] \leq \prod_{i=1}^{q-1} e^{-i/N} = e^{-\frac{1}{N} \sum_{i=1}^{q-1} i} = e^{-q(q-1)/2N}.$$

Hence  $\Pr[\exists i \neq j, y_i = y_j] \geq 1 - e^{-q(q-1)/2N}$ . Finally, if  $q \leq \sqrt{2N}$ ,  $q(q-1)/2N \leq 1$  and since  $e^{-x} \leq 1 - x/2$  for  $0 \leq x \leq 1$ , the probability is at least  $q(q-1)/4N$ .  $\square$

### Variants of the birthday bound.

Let  $y_1, \dots, y_q, z_1, \dots, z_q$  be uniformly and independently drawn from a size- $N$  set. Then

$$1 - e^{-q^2/N} \leq \Pr[\exists i, j, y_i = z_j] \leq \frac{q^2}{N}.$$

If furthermore  $q \leq \sqrt{N}$ , the lower bound is  $\geq \frac{q^2}{2N}$ .

*Proof of the upper bound.* The probability that two independent elements drawn from a size- $N$  set are equal is at most  $1/N$ . Therefore, using the union bound,  $\Pr[\exists i, j, y_i = z_j] \leq \sum_{i,j} 1/N = q^2/N$ .  $\square$

*Proof of the lower bound.* Let  $N_i$  be the event “for all  $j$ ,  $y_i \neq z_j$ .” We want to lower bound  $\Pr[\bigvee_i \neg N_i]$ , that is to upper bound  $\Pr[\bigwedge_i N_i]$ . Assume that we first draw all the values  $z_j$ ,  $1 \leq j \leq q$ . Then  $N_i$  is the event “ $y_i \notin Z$ ” where  $Z = \{z_1, \dots, z_q\}$ . Since the  $y_i$ 's are drawn independently, the  $N_i$ 's are independent events. Therefore,  $\Pr[\bigwedge_i N_i] = \prod_i \Pr[N_i]$ . Now,  $N_i = \bigvee_j [y_i = z_j]$ . Assume now on the contrary that we first draw  $y_i$ , then the  $z_j$ 's independently: We see that the events  $[y_i = z_j]$  are independent. That is  $\Pr[N_i] = \prod_j \Pr[y_i = z_j] = (1 - 1/N)^q$ . Now using  $1 + x \leq e^x$ ,  $\Pr[N_i] \leq e^{-q/N}$  and  $\Pr[\bigwedge_i N_i] \leq e^{-q^2/N}$ . Therefore,  $\Pr[\exists i, j, y_i = z_j] \geq 1 - e^{-q^2/N}$ . If  $q \leq \sqrt{N}$ ,  $q^2/N \leq 1$  and since  $e^{-x} \leq 1 - x/2$  for  $0 \leq x \leq 1$ , the probability is at least  $q^2/2N$ .  $\square$
