Background on interpolation —

**Objective**

- Geometrically, *Lagrange interpolation* consists in determining a curve (i.e., a function) that passes through predetermined positions \((x_i, y_i)\).

**Parametric case:**
Background on interpolation —

**Interpolating space** $E$

![Graph with data points and axis labels](image)
Background on interpolation —

Interpolating space $E$

- $E$: polynomials of degree 1
  - → no solution

Data: 3 points

![Graph showing data points and polynomial representation]
Interpolating space $E$

- $E$: polynomials of degree 2
  $\rightarrow$ unique solution

Data: 3 points
Background on interpolation —

Interpolating space $E$

- $E$: polynomials of degree 3
  → infinity of solutions

Data: 3 points
Background on interpolation —

Interpolating space $E$

- Trigonometric functions
  
  $$E = \text{Vect}\left\{1, \cos(\pi x), \sin(\pi x), \cos\left(\frac{\pi}{2}x\right), \sin\left(\frac{\pi}{2}x\right)\right\}$$

  $\rightarrow$ infinity of solutions

- Data: 3 points
Interpolating space $E$

- Exponential functions
  \[ E = \text{Vect}\{1, x, \exp(x), \exp(-x)\} \]
  \[ \rightarrow \text{infinity of solutions} \]

- Data: 3 points
Background on interpolation —

**Interpolating space** \( E \)

- Data: 3 points
- All solutions together
Background on interpolation —

Interpolating space $E$

- **Data**: 3 points

- **Choice of $E$**:
  - Uniqueness
  - Solution easy to evaluate? Cost?
  - Ability to fit data, etc...
Background on interpolation —

**Interpolating data (1)**

- Interpolation data from constraints, measurements...

  - Data \((x_i, y_i), 0 \leq i \leq n\) → sampling of an underlying unknown law

  - Interpolant \(P_n\) such that

    \[ P_n(x_i) = y_i \]

- Interpolation data from a function \(f\)

  - Data \((x_i, y_i = f(x_i)), 0 \leq i \leq n\) → sampling of \(f\)

  - Interpolant \(P_n(., f)\) such that

    \[ P_n(x_i, f) = f(x_i) \]
Background on interpolation —

**Interpolating data (2)**

- Interpolation data from constraints, measurements...

  ![Graph](image1)

  - Data \((x_i, y_i), 0 \leq i \leq n\)
    → sampling of an underlying unknown law
  - Interpolant \(P_n\) such that
    \[ P_n(x_i) = y_i \]

- Interpolation data from a function \(f\)

  ![Graph](image2)

  - Data \((x_i, y_i = f(x_i)), 0 \leq i \leq n\)
    → sampling of \(f\)
  - Interpolant \(P_n(., f)\) such that
    \[ P_n(x_i, f) = f(x_i) \]
Background on interpolation —

**Interpolating data (3)**

- Interpolation data from constraints, measurements...

![Interpolation data from constraints, measurements](image1)

- Interpolation data from a function $f$

![Interpolation data from a function $f$](image2)

Assumptions on the underlying unknown law are necessary for the qualitative study of the interpolation process.

Properties of the function $f$ allow qualitative study of the interpolation process.

$\rightarrow P_n(.,f)$ is an interpolant of the function $f$ at points $x_i$.
Polynomial Lagrange interpolation —

1. Background on interpolation
2. Polynomial Lagrange interpolation
3. Implementation
4. Monomial form
5. Lagrange form
6. Newton form
7. Error bounds in Lagrange interpolation
8. Chebyshev points
9. Convergence
10. Parametric interpolation
**Objective**: Polynomial Lagrange interpolation consists in determining the polynomial of the lowest possible degree passing through the points of the dataset.

- **Data**: \((x_i, y_i), \ 0 \leq i \leq n\) or \((x_i, f(x_i)), \ 0 \leq i \leq n\)
  \(\rightarrow n + 1\) distinct interpolation points \(x_i\)

- **Interpolating space** \(E: \mathbb{R}_n[x] = \{\text{polynomials of degree } \leq n\}\)
  \(\rightarrow\) \(\dim \mathbb{R}_n[x] = n + 1\)

- **Problem**: find a polynomial

\[
P_n(x) \in \mathbb{R}_n[x]: \quad P_n(x_i) = y_i, \quad 0 \leq i \leq n
\]

or identically

\[
P_n(x,f) \in \mathbb{R}_n[x]: \quad P_n(x_i,f) = f(x_i), \quad 0 \leq i \leq n
\]
Existence and uniqueness of a solution

Consider the linear map $\Phi$:

$$\begin{align*}
\mathbb{R}_n[x] & \xrightarrow{\Phi} \mathbb{R}^{n+1} \\
p & \mapsto \Phi(p) = (p(x_0), p(x_1), \ldots, p(x_n))
\end{align*}$$

Proposition 3.1

If points $x_0, x_1, \ldots, x_n$ are all distinct, the linear map $\Phi$ is bijective.

Proof

The kernel of $\Phi$ consists of polynomials of degree less than or equal to $n$ which cancel at each point $x_i$, thus admitting $n + 1$ zeros. Consequently this kernel only contains the zero polynomial and $\Phi$ is injective.

Finally, by the rank-nullity theorem

$$\dim (\mathbb{R}_n[x]) = \dim \text{Ker} (\Phi) + \dim \text{Im} (\Phi)$$

the linear map $\Phi$ is bijective.
Polynomial Lagrange interpolation —

Existence and uniqueness of a solution

Proposition 3.2

For any family of \( n + 1 \) real numbers \( y_0, y_1, \ldots, y_n \), there exists a unique polynomial \( p \in \mathbb{R}_n[x] \) satisfying the constraints

\[
p(x_i) = y_i, \quad i = 0, 1, \ldots, n.
\]

This polynomial is called the Lagrange interpolating polynomial (or simply, the interpolating polynomial) of the data \((x_i, y_i)\).

- For example, there exists
  - a unique straight line passing through 2 points with distinct abscissa,
  - a unique parabola passing through 3 points with distinct abscissa, \ldots

- It is not required for the ordinates to be distinct: there exists a unique polynomial in \( \mathbb{R}_n[x] \) passing through the \( n + 1 \) points \((x_i, y_i = 1)\) where all \( x_i \) are distinct.

- The unique interpolating polynomial of \( n + 1 \) data can be of degree strictly less than \( n \).
Implementation —

1. Background on interpolation
2. Polynomial Lagrange interpolation
3. Implementation
4. Monomial form
5. Lagrange form
6. Newton form
7. Error bounds in Lagrange interpolation
8. Chebyshev points
9. Convergence
10. Parametric interpolation
Implementation — Choice of a basis

Determination of the unique interpolating polynomial

→ depends on the basis selected to express this polynomial:
→ monomial basis: general basis
→ Lagrange basis: specifically dedicated to the Lagrange interpolation
→ Newton basis: specifically dedicated to the Lagrange interpolation

An example:

- **Monomial basis**: \( \{1, x\} \)
  \[
P_1(x) = \frac{y_0 x_1 - y_1 x_0}{x_1 - x_0} + \frac{y_1 - y_0}{x_1 - x_0} x
\]
  \( P_1(x) = 4 - x \)

- **Lagrange basis**: \( \{\frac{x-x_1}{x_0-x_1}, \frac{x-x_0}{x_1-x_0}\} \)
  \[
P_1(x) = y_0 \frac{x-x_1}{x_0-x_1} + y_1 \frac{x-x_0}{x_1-x_0}
\]
  \( P_1(x) = 3 \frac{x-3}{-2} + \frac{x-1}{2} \)

- **Newton basis**: \( \{1, x - x_0\} \)
  \[
P_1(x) = y_0 + \frac{y_1 - y_0}{x_1 - x_0} (x - x_0)
\]
  \( P_1(x) = 3 - (x - 1) \)
Monomial form —

1. Background on interpolation
2. Polynomial Lagrange interpolation
3. Implementation
4. Monomial form
5. Lagrange form
6. Newton form
7. Error bounds in Lagrange interpolation
8. Chebyshev points
9. Convergence
10. Parametric interpolation
Monomial form — Identification of the interpolant

Let \( p(x) \) be a \( n \)-degree polynomial expressed in the monomial basis

\[
p(x) = a_0 + a_1 x + a_2 x^2 + \cdots + a_n x^n
\]

The \( n + 1 \) interpolation constraints \( p(x_i) = y_i \) lead to the \((n + 1) \times (n + 1)\) linear system

\[
\begin{align*}
    a_0 + a_1 x_0 + a_2 x_0^2 + \cdots + a_n x_0^n &= y_0 \\
    a_0 + a_1 x_1 + a_2 x_1^2 + \cdots + a_n x_1^n &= y_1 \\
    a_0 + a_1 x_2 + a_2 x_2^2 + \cdots + a_n x_2^n &= y_2 \\
    \vdots & \quad \vdots & \quad \vdots & \quad \vdots \\
    a_0 + a_1 x_n + a_2 x_n^2 + \cdots + a_n x_n^n &= y_n
\end{align*}
\]

which can be written in matrix form

\[
\begin{pmatrix}
    1 & x_0 & x_0^2 & \cdots & x_0^n \\
    1 & x_1 & x_1^2 & \cdots & x_1^n \\
    1 & x_2 & x_2^2 & \cdots & x_2^n \\
    \vdots & \vdots & \vdots & \ddots & \vdots \\
    1 & x_n & x_n^2 & \cdots & x_n^n \\
\end{pmatrix}
\begin{pmatrix}
    a_0 \\
    a_1 \\
    a_2 \\
    \vdots \\
    a_n
\end{pmatrix}
=
\begin{pmatrix}
    y_0 \\
    y_1 \\
    y_2 \\
    \vdots \\
    y_n
\end{pmatrix}
\]
The matrix of this system is called the Vandermonde matrix. Its determinant (the Vandermonde determinant) is

$$\prod_{0 \leq i < j \leq n} (x_j - x_i)$$

which is obviously non zero if and only if the points $x_i$ are all distinct (which proves again the existence and the uniqueness of a solution).

- Unfortunately, the numerical resolution of this Vandermonde system is intricate, costly and numerically unstable. Indeed, this linear system is ill-conditioned, which means that a small error on the coefficients or on the second member leads to a major error on the solution of the system.

- In conclusion, the monomial basis is not recommended for the calculation of the interpolating polynomial.

- Note that the evaluation of a polynomial expressed in the canonical basis has to be performed by means of the Horner scheme.
Monomial form — Horner scheme

Algorithms involving polynomials, and in particular plotting the graph of a polynomial function over an interval \([a, b]\), require the evaluation of \(p(t_i)\) for many values \(t_i = a + i \cdot (b - a) / N\), \(i = 0, 1, \ldots, N\), which justify the interest of developing efficient algorithms for such evaluations.

- **Naive algorithm**: requires \(2n\) multiplications for the evaluation of \(p(x)\).
  
  Let
  
  \[
  p(x) = a_0 + a_1 x + a_2 x^2 + \cdots + a_n x^n
  \]

  ```
  #initialization data:
  # x = a real number
  # a = (a[0], a[1], ..., a[n]) = vector of polynomial coeffs
  xn = 1
  p = a[0]
  for i = 1 until n do  # n steps
    xn = xn * x  # 1 multiplication
    p = p + a[i] * xn  # 1 multiplication
  endfor
  return p  # p = p(x)
  ```
Algorithms involving polynomials, and in particular plotting the graph of a polynomial function over an interval \([a, b]\), require the evaluation of \(p(t_i)\) for many values \(t_i = a + i \times (b - a)/N\), \(i = 0, 1, \ldots, N\), which justify the interest of developing efficient algorithms for such evaluations.

**Horner scheme**: requires only \(n\) multiplications for the evaluation of \(p(x)\).

The Horner scheme (also named the Ruffini-Horner’s method) is based on the following factorization, illustrated here with a polynomial of degree 4

\[
p(x) = a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4
\]

\[
= a_0 + x \left( a_1 + x \left( a_2 + x \left( a_3 + x (a_4) \right) \right) \right)
\]

```plaintext
#initialization data:
# x = a real number
# a = (a[0],a[1],...,a[n]) = vector of polynomial coeffs
p = a[n]
for i = n-1 until 0 with step = -1 do  # n steps
    p = a[i] + x * p  # 1 multiplication
endfor
return p  # p = p(x)
```
Lagrange form —

10. Parametric interpolation
Lagrange polynomials \( L_i(x) \) associated with the \( n + 1 \) distinct points 
\[ x_0, x_1, x_2, \ldots, x_n, \]
are defined by
\[
L_i(x) = \prod_{0 \leq j \leq n \atop j \neq i} \frac{x - x_j}{x_i - x_j}, \quad 0 \leq i \leq n.
\]
For \( n = 0 \), the unique Lagrange polynomial is \( L_0(x) = 1, \ x \in \mathbb{R} \).

The six Lagrange polynomials \( L_k(x) \) of degree 5, associated with 6 points uniformly distributed in the interval \([-2, 4]\).
Proposition 3.3
For $0 \leq i, j \leq n$, we have
\[ L_i(x_j) = \delta_{ij}. \]

Proposition 3.4 (Lagrange basis)
The $n + 1$ Lagrange polynomials $L_i(x)$, $0 \leq i \leq n$, form a basis of $\mathbb{R}_n[x]$, referred as the Lagrange basis (relative to points $x_i$ or associated with points $x_i$).

Proof
Clearly $L_i(x) \in \mathbb{R}_n[x]$ for each $i$.
Then, since $\dim \mathbb{R}_n[x] = n + 1$, we just need to prove that the $n + 1$ polynomials $L_i(x)$ are linearly independent. Consider thus a linear combination equal to zero:
\[ \sum_{i=0}^{n} \alpha_i L_i(x) = 0, \quad \forall x \in \mathbb{R}. \]

For $x = x_j$, $0 \leq j \leq n$, we have $\sum_{i=0}^{n} \alpha_i L_i(x_j) = \sum_{i=0}^{n} \alpha_i \delta_{ij} = \alpha_j = 0$. We thus deduce that $\alpha_0 = \alpha_1 = \cdots = \alpha_n = 0$, which proves that polynomials $L_i(x)$ are linearly independent and thus form a basis of $\mathbb{R}_n[x]$. 
Proposition 3.5

The interpolating polynomial \( p(x) \) associated with data \( (x_i, y_i) \) is expressed in the Lagrange basis as follows

\[
p(x) = \sum_{i=0}^{n} y_i \ L_i(x).
\]

Proof

A straightforward inspection shows that \( p(x) \in \mathbb{R}_n[x] \) and that \( p(x_i) = y_i \) for \( i = 0, \ldots, n \).

This polynomial is named the interpolating polynomial in the Lagrange basis.

- Despite the simple writing of the interpolating polynomial, the basis of Lagrange is not always the best suited to calculations.
- Indeed, each polynomial \( L_k(x) \) depends on the set of all interpolation points \( x_i \).
- The use of Lagrange basis is relevant when several interpolations associated with the same interpolation data set \( x_i \) have to be performed (which means that only data \( y_i \) change).
- If an interpolation point \( x_i \) is added or modified, all calculations must be fully resumed.
Lagrange form — Example

Consider the function $f(x) = 4 - x - 4x^2 + x^3$ and the following interpolation data set.

<table>
<thead>
<tr>
<th>$x_0 = 1$</th>
<th>$x_1 = 3$</th>
<th>$x_2 = -1$</th>
<th>$x_3 = 2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$y_0 = f(x_0) = 0$</td>
<td>$y_1 = f(x_1) = -8$</td>
<td>$y_2 = f(x_2) = 0$</td>
<td>$y_3 = f(x_3) = -6$</td>
</tr>
</tbody>
</table>

We first interpolate $f$ at point $x_0$. Then we successively add interpolation points $x_1$, $x_2$ and $x_3$. We thus get the three interpolating polynomials $P_k(x, f)$ ($k = 0, 1, 2, 3$), associated with data $(x_i, f(x_i))$, $0 \leq i \leq k$.

\[
P_0(x, f) = y_0 L_0(x) = y_0 = 0 \quad = 0
\]

\[
P_1(x, f) = y_0 \frac{x - x_1}{x_0 - x_1} + y_1 \frac{x - x_0}{x_1 - x_0} = 0 \frac{x - 3}{1 - 3} + (-8) \frac{x - 1}{3 - 1} \quad = 4 - 4x
\]

\[
P_2(x, f) = y_0 \frac{(x - x_1)(x - x_2)}{(x_0 - x_1)(x_0 - x_2)} + y_1 \frac{(x - x_0)(x - x_2)}{(x_1 - x_0)(x_1 - x_2)} + y_2 \frac{(x - x_0)(x - x_1)}{(x_2 - x_0)(x_2 - x_1)} = 0 \frac{(x - 3)(x + 1)}{-4} + (-8) \frac{(x - 1)(x + 1)}{8} + 0 \frac{(x - 1)(x - 3)}{8} \quad = 1 - x^2
\]

\[
P_3(x, f) = y_0 \frac{(x - x_1)(x - x_2)(x - x_3)}{(x_0 - x_1)(x_0 - x_2)(x_0 - x_3)} + y_1 \frac{(x - x_0)(x - x_2)(x - x_3)}{(x_1 - x_0)(x_1 - x_2)(x_1 - x_3)} + y_2 \frac{(x - x_0)(x - x_1)(x - x_3)}{(x_2 - x_0)(x_2 - x_1)(x_2 - x_3)} + y_3 \frac{(x - x_0)(x - x_1)(x - x_2)}{(x_3 - x_0)(x_3 - x_1)(x_3 - x_2)} = 4 - x - 4x^2 + x^3
\]
Consider the function $f(x) = 4 - x - 4x^2 + x^3$ and the following interpolation data set.

<table>
<thead>
<tr>
<th>$x_0 = 1$</th>
<th>$x_1 = 3$</th>
<th>$x_2 = -1$</th>
<th>$x_3 = 2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$y_0 = f(x_0) = 0$</td>
<td>$y_1 = f(x_1) = -8$</td>
<td>$y_2 = f(x_2) = 0$</td>
<td>$y_3 = f(x_3) = -6$</td>
</tr>
</tbody>
</table>

We first interpolate $f$ at point $x_0$. Then we successively add interpolation points $x_1$, $x_2$, and $x_3$. We thus get the three interpolating polynomials $P_k(x,f)$ ($k = 0, 1, 2, 3$), associated with data $(x_i,f(x_i))$, $0 \leq i \leq k$.

- Notice that $P_3(x,f) = f(x)$, which is natural since these two polynomials of degree 3 coincide in 4 distinct values.
- There is no apparent link in polynomial expressions of $P_k(x,f)$ and $P_{k+1}(x,f)$ in Lagrange basis.
Proposition 3.6 (Additional properties of Lagrange polynomials)

1. **Partition of unity :**

   $\sum_{i=0}^{n} L_i(x) = 1$

2. **For $1 \leq j \leq n$ :**

   $\sum_{i=0}^{n} x_i^j L_i(x) = x^j$

3. **For $1 \leq j \leq n$ :**

   $\sum_{i=0}^{n} (x - x_i)^j L_i(x) = 0$

4. **Derivatives for $0 \leq i \leq n$ :**

   $L_i'(x) = L_i(x) \left( \sum_{j=0}^{n} \frac{1}{x - x_j} \right) = \frac{1}{\prod_{j=0}^{n} (x_i - x_j)} \sum_{j=0}^{n} \left( \prod_{k=0}^{n} (x - x_k) \right)_{k \neq i,j}$

Specify the values of the derivatives $L_i'(x_i)$ and $L_i'(x_j)$, $j \neq i$. 
Newton form —

1. Background on interpolation
2. Polynomial Lagrange interpolation
3. Implementation
4. Monomial form
5. Lagrange form
6. Newton form
7. Error bounds in Lagrange interpolation
8. Chebyshev points
9. Convergence
10. Parametric interpolation
Newton polynomials associated with the $n + 1$ distinct points $x_0, x_1, x_2, \ldots, x_n$, are defined as follows:

\[
\begin{align*}
N_0(x) &= 1, \\
N_1(x) &= x - x_0, \\
N_2(x) &= (x - x_0)(x - x_1), \\
&\vdots \\
N_n(x) &= (x - x_0)(x - x_1) \cdots (x - x_{n-1}).
\end{align*}
\]

These polynomials are thus determined by the first polynomial $N_0(x)$ and the recurrence relation

\[
N_{k+1}(x) = (x - x_k)N_k(x), \quad k = 0, 1, \ldots, n - 1.
\]

- Note that the definition of each polynomial $N_k(x)$ does not involve the interpolation point $x_k$.

- In particular, point $x_n$ does not participate in the definition of the whole base. But of course, the point $x_n$ will contribute to the computation of the interpolation polynomial with respect to the Newton base.
Newton form — Newton basis

Proposition 3.7 (Newton basis)

Newton polynomials

\[ N_i(x), \quad 0 \leq i \leq n, \]

form a basis of \( \mathbb{R}_n[x] \), referred as the Newton basis relative to (or associated with) points \( x_i \).

Proof

Since \( \dim \mathbb{R}_n[x] = n + 1 \), we just need to prove that the \( n + 1 \) polynomials \( N_i(x) \) are linearly independent. Consider thus a linear combination equal to zero for all \( x \)

\[ \sum_{i=0}^{n} \alpha_i N_i(x) = 0, \quad \forall x \in \mathbb{R}. \]

For \( x = x_0 \), we get \( \sum_{i=0}^{n} \alpha_i N_i(x_0) = \alpha_0 = 0. \) Then, considering successively values \( x_1, x_2, \ldots, x_n \), we deduce that \( \alpha_1 = \alpha_2 = \cdots = \alpha_n = 0 \), which proves that the family of polynomials \( N_i(x) \) is linearly independent and thus is a basis of \( \mathbb{R}_n[x] \).
Newton form — Identification of the interpolant

**Objective** : determination of the coefficients $\delta_0, \delta_1, \ldots, \delta_n$ such that the polynomial

$$P_n(x) = \delta_0 N_0(x) + \delta_1 N_1(x) + \delta_2 N_2(x) + \cdots + \delta_n N_n(x)$$

satisfies $P_n(x_i) = y_i, \quad i = 0, 1, \ldots, n$.

**Determination of the first coefficients $\delta_0, \delta_1, \delta_2$ :**

<table>
<thead>
<tr>
<th>Interpolating polynomial</th>
<th>constraints</th>
<th>coefficients $\delta_k$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$P_0(x)$</td>
<td>$P_0(x_0) = y_0$</td>
<td>$\delta_0 = y_0$</td>
</tr>
<tr>
<td>$P_0(x)$</td>
<td>$P_0(x_0) = y_0$</td>
<td>$\delta_0 = y_0$</td>
</tr>
<tr>
<td>$P_1(x)$</td>
<td>$P_1(x_1) = y_1$</td>
<td>$\delta_1 = \frac{y_1 - y_0}{x_1 - x_0}$</td>
</tr>
<tr>
<td>$P_2(x)$</td>
<td>$P_2(x_1) = y_1$</td>
<td>$\delta_1 = \frac{y_1 - y_0}{x_1 - x_0}$</td>
</tr>
<tr>
<td>$P_2(x)$</td>
<td>$P_2(x_2) = y_2$</td>
<td>$\delta_2 = \frac{y_2 - y_1}{x_2 - x_1} - \frac{y_1 - y_0}{x_1 - x_0}$</td>
</tr>
</tbody>
</table>

| Calculation detail : $P_2(x_2) = y_2$ $\Rightarrow$ $y_0 + \frac{y_1 - y_0}{x_1 - x_0}(x_2 - x_0) + \delta_2^2 (x_2 - x_0)(x_2 - x_1) = y_2$ $\Rightarrow$ $\delta_2^2 (x_2 - x_0)(x_2 - x_1)(x_1 - x_0)$

$$= (y_2 - y_1 + y_1 - y_0)(x_1 - x_0) - (y_1 - y_0)(x_2 - x_1 + x_1 - x_0)$$

$$= (y_2 - y_1)(x_1 - x_0) - (y_1 - y_0)(x_2 - x_1)$$
Newton form — Identification of the interpolant

**Objective:** determination of the coefficients $\delta_0, \delta_1, \ldots, \delta_n$ such that the polynomial

$$P_n(x) = \delta_0 N_0(x) + \delta_1 N_1(x) + \delta_2 N_2(x) + \cdots + \delta_n N_n(x)$$

satisfies $P_n(x_i) = y_i, \ i = 0, 1, \ldots, n$.

with \(\delta[x_j, x_{j+1}, \ldots, x_{j+p}] := \frac{\delta[x_{j+1}, \ldots, x_{j+p}] - \delta[x_j, \ldots, x_{j+p-1}]}{x_{j+p} - x_j}\), \(1 \leq p \leq k, \ 0 \leq j \leq k-p\)
Newton form — Identification of the interpolant

Proof of Newton formula

Step 1.
Proposition 3.9 (Neville formula)

Let \( P_{i,p}(x) \) be the interpolating polynomial at points \( x_i, x_{i+1}, \ldots, x_{i+p} \)

\[
P_{i,p}(x) = \frac{x - x_i}{x_{i+p} - x_i} P_{i+1,p-1}(x) + \frac{x_{i+p} - x}{x_{i+p} - x_i} P_{i,p-1}(x) \quad \text{for} \quad 1 \leq p \leq n \quad 0 \leq i \leq n - p
\]

Proof (of Neville formula)

Both sides of Neville formula are of degree \( p \) and agree for the \( p + 1 \) points \( x_i, x_{i+1}, \ldots, x_{i+p} \), which proves the result by uniqueness of the interpolating polynomial.

Step 2.

Proof of relation \( P_k(x) = P_{k-1}(x) + \delta_k N_k(x) \):

By definition we have \( P_k(x_j) = P_{k-1}(x_j) = y_j \) for \( j = 0, \ldots, k - 1 \),
which proves that \( P_k(x) - P_{k-1}(x) \) is a multiple of \( (x - x_0) \cdots (x - x_{k-1}) = N_k(x) \).
Finally, by degree analysis we get

\[
P_k(x) - P_{k-1}(x) = \delta_k N_k(x) \quad \text{with} \quad \delta_k \in \mathbb{R}
\]
Newton form — Identification of the interpolant

Step 3. Proof of Newton formula by induction on the degree $k$

- Newton formula has already been verified for $k = 0$, $k = 1$, $k = 2$
- Assume that the formula holds for any interpolating polynomial of degree $k - 1$, with $k - 1 \geq 0$, which allows to write

$$P_{0,k-1}(x) = P_{0,k-2}(x) + \delta[x_0, \ldots, x_{k-1}] (x - x_0) \cdots (x - x_{k-2})$$
$$P_{1,k-1}(x) = P_{1,k-2}(x) + \delta[x_1, \ldots, x_k] (x - x_1) \cdots (x - x_{k-1})$$

Then, by Neville’s formula, we get

$$P_k(x) = P_{0,k}(x) = \frac{x - x_0}{x_k - x_0} P_{1,k-1}(x) + \frac{x_k - x}{x_k - x_0} P_{0,k-1}(x)$$

$$= \frac{x - x_0}{x_k - x_0} \left( P_{1,k-2}(x) + \delta[x_1, \ldots, x_k] (x - x_1) \cdots (x - x_{k-1}) \right)$$
$$+ \frac{x_k - x}{x_k - x_0} \left( P_{0,k-2}(x) + \delta[x_0, \ldots, x_{k-1}] (x - x_0) \cdots (x - x_{k-2}) \right)$$

$$= \frac{(x - x_0)P_{1,k-2}(x) + (x_k - x)P_{0,k-2}(x)}{x_k - x_0}$$
$$+ \frac{\delta[x_1, \ldots, x_k] (x - x_0)(x - x_1) \cdots (x - x_{k-1})}{x_k - x_0}$$
$$+ \frac{\delta[x_0, \ldots, x_{k-1}] (x - x_0) \cdots (x - x_{k-2})(x_k - x_{k-1} + x_{k-1} - x)}{x_k - x_0}$$

$$= \underbrace{\cdots \cdots}_{\text{degree } k-1} + \frac{\delta[x_1, \ldots, x_k] - \delta[x_0, \ldots, x_{k-1}]}{x_k - x_0} \delta[x_0, \ldots, x_k] N_k(x)$$

which concludes the proof
**Newton form — Example**

**Example**

Consider the function \( f(x) = 4 - x - 4x^2 + x^3 \) and the following interpolation data set.

<table>
<thead>
<tr>
<th>( x_i )</th>
<th>( y_i = f(x_i) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>-8</td>
</tr>
<tr>
<td>-1</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>-6</td>
</tr>
</tbody>
</table>

We determine interpolating polynomials \( P_k(x, f) \) for \( k = 0, 1, 2, 3 \), associated with data \((x_i, f(x_i)), 0 \leq i \leq k\).

We first calculate the associated divided differences that are noted in that case \( f[x_j, \ldots, x_{j+p}] \) instead of \( \delta[x_j, \ldots, x_{j+p}] \)

<table>
<thead>
<tr>
<th>( x_i )</th>
<th>order 0</th>
<th>order 1</th>
<th>order 2</th>
<th>order 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>( y_0 = 0 = f[x_0] )</td>
<td>( \frac{-8-0}{3-1} = -4 = f[x_0, x_1] )</td>
<td>( \frac{-2-(-4)}{2-1} = -1 = f[x_0, x_1, x_2] )</td>
<td>( \frac{0-(-1)}{2-1} = 1 = f[x_0, \ldots, x_3] )</td>
</tr>
<tr>
<td>3</td>
<td>( y_1 = -8 = f[x_1] )</td>
<td>( \frac{0-(-8)}{1-3} = -2 = f[x_1, x_2] )</td>
<td>( \frac{-2-(-2)}{2-3} = 0 = f[x_1, x_2, x_3] )</td>
<td></td>
</tr>
<tr>
<td>-1</td>
<td>( y_2 = 0 = f[x_2] )</td>
<td>( \frac{-6-0}{2-(-1)} = -2 = f[x_2, x_3] )</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>( y_3 = -6 = f[x_3] )</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

\[
P_0(x, f) = f[x_0] N_0(x) = 0
\]
\[
P_1(x, f) = P_0(x, f) + f[x_0, x_1] N_1(x) = 0 + (-4)(x - 1)
\]
\[
P_2(x, f) = P_1(x, f) + f[x_0, x_1, x_2] N_2(x) = 0 + (-4)(x - 1) + (-1)(x - 1)(x - 3)
\]
\[
P_3(x, f) = P_2(x, f) + f[x_0, x_1, x_2, x_3] N_3(x) = 0 + (-4)(x - 1) + (-1)(x - 1)(x - 3) + 1(x - 1)(x - 3)(x + 1)
\]
Proposition 3.10 (Additional properties of DD)

1. Expanded form:
\[ \delta[x_0, x_1, \ldots, x_k] = \sum_{j=0}^{k} \frac{y_j}{\prod_{i=0, i \neq j} (x_j - x_i)} , \quad 0 \leq k \leq n. \]

2. Symmetry: divided differences do not depend on the order of the data, that is
\[ \delta[x_{\sigma(0), x_{\sigma(1)}, \ldots, x_{\sigma(k)}]} = \delta[x_0, x_1, \ldots, x_k] \]
for all permutation \( \sigma \) of the set \( \{0, 1, \ldots, k\}, \ 0 \leq k \leq n. \)

3. Linearity: if \( f = \lambda g + \mu h \), where \( g \) and \( h \) are two functions defined on an interval \( [a, b] \) which contains all the points \( x_i \), then
\[ f[x_0, x_1, \ldots, x_k] = \lambda g[x_0, x_1, \ldots, x_k] + \mu h[x_0, x_1, \ldots, x_k], \quad 0 \leq k \leq n. \]

4. Derivatives and mean value theorem.
Assuming that the function \( f \) is sufficiently smooth, we have
\[ f[x_0, x_1, \ldots, x_k] = \frac{f^{(k)}(\xi)}{k!} \quad \text{where} \ \xi \in (\min(x_i), \max(x_i)), \quad 0 \leq k \leq n. \]
Newton form — Exercises

Horner scheme for Newton basis

Exercise 3.1 — Write the Horner scheme for a polynomial expressed in Newton basis. For this purpose, consider the following factorization of a polynomial expressed in Newton basis (relative to interpolation points $x_i$)

$$P_3(x) = \delta_0 N_0(x) + \delta_1 N_1(x) + \delta_2 N_2(x) + \delta_3 N_3(x)$$

$$= \delta_0 \cdot 1 + \delta_1 (x - x_0) + \delta_2 (x - x_0)(x - x_1) + \delta_3 (x - x_0)(x - x_1)(x - x_2)$$

$$= \delta_0 + (x - x_0)\left(\delta_1 + (x - x_1)\left(\delta_2 + (x - x_2)(\delta_3)\right)\right)$$

#initialization data:
# x = a real number
# d = (d[0],d[1],...,d[n]) = vector of polynomial coeffs (DD)
# xi = (xi[0],xi[1],...,xi[n]) = vector of interpolating points
# p = ... # initialization
# for ...
# ... # initialization
# return p # p = p(x)
Newton form — Exercises

Calculation of divided differences

Exercise 3.2 —
1) Write a Python function `diffdiv(xi, yi)` enabling the computation of divided differences with a one-dimensional vector `delta`.
   
   Input data: (xi, yi), i = 0, 1, ..., n
   Output data: `delta = (δ[x_0], δ[x_0, x_1], ..., δ[x_0, x_1, ..., x_n], ..., δ[x_{n-1}, x_n], δ[x_n])`

2) Write a Python function `updateDD(xi, yi, delta, xnew, ynew)` enabling the update of the vector `delta` of divided differences in case of a new data `(xnew, ynew)`.

Hints: (a) Duplicate the vector `yi` into the vector `delta` by inserting a zero between each consecutive element `y_i` and `y_{i+1}`, so as to get a vector of size `2n + 1`. (b) Take inspiration from the table below, where each calculated divided difference is stored at its line index.

<table>

Error bounds in Lagrange interpolation —

1. Background on interpolation
2. Polynomial Lagrange interpolation
3. Implementation
4. Monomial form
5. Lagrange form
6. Newton form
7. Error bounds in Lagrange interpolation
8. Chebyshev points
9. Convergence
10. Parametric interpolation
Error bounds in Lagrange interpolation — Objective

- **Error:**

\[ E_n = \max_{x \in [a, b]} |P_n(x, f) - f(x)| \]

\[ a = \min x_i, \ b = \max x_i \]

- **Choice of interpolation data:**

\[ n \in \mathbb{N}, \ \min_{x_i \in [a, b]} (E_n) = \min_{x_i \in [a, b]} \left( \max_{x \in [a, b]} |P_n(x, f) - f(x)| \right) \]

Optimal distribution: Chebyshev points

- **Convergence:**

\[ \lim_{n \to \infty} E_n \]
Proposition 3.11 (error bounds in Lagrange interpolation)

Let \( f \in C^{n+1}[a, b] \), \( n + 1 \) distinct points \( x_0, x_1, \ldots, x_n \) in \([a, b]\) and \( P_n(x, f) \) the interpolating polynomial of \( f \) associated with these data points. Then,

\[
\forall x \in [a, b], \exists \xi_x \in ]a, b[, \quad f(x) - P_n(x, f) = \prod_{i=0}^{n} (x - x_i) \left( \frac{f^{(n+1)}(\xi_x)}{(n + 1)!} \right)
\]

Thus,

\[
\forall x \in [a, b], \quad |f(x) - P_n(x, f)| \leq \frac{\prod_{i=0}^{n} (x - x_i)}{(n + 1)!} \max_{a \leq \xi \leq b} |f^{(n+1)}(\xi)| \quad (3)
\]

Finally, with \( \Pi_{n+1}(x) = \prod_{i=0}^{n} (x - x_i) \), we get

\[
\left\| f - P_n(., f) \right\| := \max_{x \in [a, b]} |f(x) - P_n(x, f)| \leq \frac{\left\| \Pi_{n+1} \right\|}{(n + 1)!} \left\| f^{(n+1)} \right\| \quad (4)
\]
Proof (error bounds in Lagrange interpolation)

Let \( x \in [a, b] \) be a real value different from each of the points \( x_i \), and consider the function

\[
\phi_x(u) = f(u) - P_n(u, f) - \left( f(x) - P_n(x, f) \right) \frac{\prod_{i=0}^{n}(u - x_i)}{\prod_{i=0}^{n}(x - x_i)}, \quad u \in [a, b],
\]

which is clearly of class \( C^{n+1} \) on \([a, b]\).

Function \( \phi_x \) vanishes at each point \( x_i \) and at point \( x \), and thus admits \( n + 2 \) zeros in the interval \([a, b]\). Therefore, with Rolle’s theorem we deduce by induction that the function \( \phi^{(n+1)}_x \) vanishes at one point \( \xi \) in \([a, b]\), that is \( \exists \xi \in ]a, b[, \phi^{(n+1)}_x(\xi) = 0 \).

The \((n+1)\)-th derivative of the polynomial \( P_n(u, f) \) is identically zero and the \((n+1)\)-th derivative of the \((n+1)\)-degree polynomial \( \prod_{i=0}^{n}(u - x_i) \) is constant and equal to \((n+1)!\), so that

\[
\phi^{(n+1)}_x(\xi) = f^{(n+1)}(\xi) - \left( f(x) - P_n(x, f) \right) \frac{(n + 1)!}{\prod_{i=0}^{n}(x - x_i)} = 0,
\]

which leads to

\[
f(x) - P_n(x, f) = \frac{\prod_{i=0}^{n}(x - x_i)}{(n + 1)!} f^{(n+1)}(\xi).
\]

This relation is also valid for \( x = x_i, \ i = 0, 1, \ldots, n \), which concludes the proof.
Error bounds in Lagrange interpolation — Main result

Formula

\[ \| f - P_n(.,f) \| := \max_{x \in [a,b]} \| f(x) - P_n(x,f) \| \leq \frac{\| \Pi_{n+1} \|}{(n + 1)!} \| f^{(n+1)} \| \]

shows that the error depends on the function \( f \) and on the norm \( \| \Pi_{n+1} \| \) which is related to the repartition of the interpolation points \( x_i \) in the interval \([a, b]\).

- If we have no information on the distribution of points \( x_i \), the best estimation is
  \[ \| \Pi_{n+1} \| \leq (b - a)^{n+1}. \]

- In case of evenly spaced points \( x_i \) in \([a, b]\), one can prove that
  \[ \| \Pi_{n+1} \| \leq \left( \frac{b - a}{e} \right)^{n+1}. \]

- The best possible distribution of the interpolation points consists in the Chebyshev points (that will be introduced later) and leads to the optimal estimation
  \[ \| \Pi_{n+1} \| \leq 2 \left( \frac{b - a}{4} \right)^{n+1}, \]
  which represents a substantial gain.

For example, for \( n = 20 \) the ratio \( 2 \left( \frac{b - a}{4} \right)^{n+1} / \left( \frac{b - a}{e} \right)^{n+1} < 6.10^{-4} \), so that interpolation at Chebyshev points significantly improves the accuracy compared with interpolation at evenly spaced points.
Chebyshev points —

1. Background on interpolation
2. Polynomial Lagrange interpolation
3. Implementation
4. Monomial form
5. Lagrange form
6. Newton form
7. Error bounds in Lagrange interpolation
8. Chebyshev points
9. Convergence
10. Parametric interpolation
Chebyshev points — Objective

- **Error**: 
  \[ E_n = \max_{x \in [a, b]} |P_n(x, f) - f(x)| \]

- **Choice of interpolation data**: 
  \[ a = \min x_i, \ b = \max x_i \]

- **Convergence**: 
  \[ \lim_{n \to \infty} E_n = ? \]
Objective: determine the best distribution of interpolation points $x_i$ in the interval $[a, b]$ so as to minimize the norm $||\Pi_{n+1}||$.

- We first study the problem on the symmetric interval $[-1, 1]$, from which we then deduce the solution over any interval $[a, b]$ by an affine transformation.

- Statement of the problem:
  determine a strictly increasing sequence of $n + 1$ points $x_i$:

$$-1 \leq x_0 < x_1 < \cdots < x_{n-1} < x_n \leq 1$$

so as to minimize the norm $||\Pi_{n+1}||$, that is

$$\min_{x_i} \left( \max_{x \in [-1,1]} \left| (x - x_0)(x - x_1) \cdots (x - x_n) \right| \right) ||\Pi_{n+1}||$$

We will first look at some basic examples ($n = 0, n = 1, n = 2$). The general solution is based on Chebyshev polynomials.

---

1. Pafnuty Lvovich Chebyshev (1821–1894), Russian mathematician.
Chebyshev points — Basic examples

Basic examples:

- **Case** $n = 0$: $\Pi_{0+1}(x) = (x - x_0)$ with $x_0 \in [-1, 1]$
  
  **Solution**: $x_0 = 0$ and $\Pi_{0+1}(x) = x - 0 = x$

- **Case** $n = 1$: $\Pi_{1+1}(x) = (x - x_0)(x - x_1)$ with $-1 \leq x_0 < x_1 \leq 1$
  
  **Solution**: $x_0 = -\frac{1}{\sqrt{2}}$, $x_1 = \frac{1}{\sqrt{2}}$ and $\Pi_{1+1}(x) = (x + \frac{1}{\sqrt{2}})(x - \frac{1}{\sqrt{2}}) = x^2 - \frac{1}{2}$

- **Case** $n = 2$: $\Pi_{2+1}(x) = (x - x_0)(x - x_1)(x - x_2)$ with $-1 \leq x_0 < x_1 < x_2 \leq 1$
  
  **Solution**: $x_0 = -\frac{\sqrt{3}}{2}$, $x_1 = 0$, $x_2 = \frac{\sqrt{3}}{2}$
  
  and $\Pi_{2+1}(x) = (x + \frac{\sqrt{3}}{2})x(x - \frac{\sqrt{3}}{2}) = x^3 - \frac{3}{4}x$

Note that for each optimal solution $\Pi_{n+1}(x)$, $(n = 0, 1, 2)$, the maximum is reached exactly $n + 2$ times over the interval $[-1, 1]$. 

\[
\begin{align*}
\Pi_{0+1}(x) &= x - 0 \\
&= x - \cos \frac{\pi}{2}
\end{align*}
\]
\[
\begin{align*}
\Pi_{1+1}(x) &= (x - \frac{1}{\sqrt{2}})(x + \frac{1}{\sqrt{2}}) \\
&= (x - \cos \frac{\pi}{4})(x - \cos \frac{3\pi}{4})
\end{align*}
\]
\[
\begin{align*}
\Pi_{2+1}(x) &= (x - \frac{\sqrt{3}}{2})(x - 0)(x + \frac{\sqrt{3}}{2}) \\
&= (x - \cos \frac{\pi}{6})(x - \cos \frac{3\pi}{6})(x - \cos \frac{5\pi}{6})
\end{align*}
\]
Chebyshev points — Chebyshev polynomials

**Chebyshev polynomials:** The study of Chebyshev polynomials is presented in the form of a problem. The Chebyshev polynomial of degree \( n \) is defined by

\[
T_n(x) = \cos (n \, \arccos(x)), \quad x \in [-1, 1].
\]

1. Determine \( T_0(x) \) and \( T_1(x) \).
2. Compute \( T_{n+1}(x) + T_{n-1}(x) \) and derive the following recursive relation

\[
T_{n+1}(x) = 2x T_n(x) - T_{n-1}(x), \quad n \geq 1.
\]
3. Compute the Chebyshev polynomials \( T_n(x) \) for \( n \leq 5 \).
4. Deduce that \( T_n(x) \) is a polynomial of degree \( n \) whose leading term is \( 2^{n-1}x^n \) for \( n \geq 1 \).
5. Show that \( T_n(x) \) is even if \( n \) is even and is odd if \( n \) is odd.
6. Prove that \( T_n(x) \) has \( n \) simple roots \( r_k \) in the interval \([-1, 1]\) and specify these roots as functions of \( n \) and \( k \) (the Chebyshev points of order \( n \) relative to the interval \([-1, 1]\)).
7. Check that for all \( x \) in \([-1, 1]\), \(|T_n(x)| \leq 1\), and show that \(|T_n(x)| = 1\) for \( n + 1 \) distinct values of \( x \) in \([-1, 1]\). Specify these values.
8. Demonstrate that Chebyshev polynomials are orthogonal relative to the following scalar product:

\[
\int_{-1}^{1} T_n(x) T_p(x) \frac{1}{\sqrt{1-x^2}} \, dx = \begin{cases} 
0 & \text{if } n \neq p \\
\pi & \text{if } n = p = 0 \\
\pi/2 & \text{if } n = p \neq 0
\end{cases}
\]

Use the change of variable \( x = \cos(u) \) and we recall that \( \arccos'(x) = \frac{-1}{\sqrt{1-x^2}} \).
Chebyshev points — Chebyshev polynomials

**Chebyshev polynomials:** The study of Chebyshev polynomials is presented in the form of a problem. The Chebyshev polynomial of degree $n$ is defined by

$$T_n(x) = \cos \left( n \arccos(x) \right), \quad x \in [-1, 1].$$

3. Compute the Chebyshev polynomials $T_n(x)$ for $n \leq 5$.

6. Prove that $T_n(x)$ has $n$ simple roots $r_k$ in the interval $[-1, 1]$ and specify these roots as functions of $n$ and $k$ (the Chebyshev points of order $n$ relative to the interval $[-1, 1]$).

7. Check that for all $x$ in $[-1, 1]$, $|T_n(x)| \leq 1$, and show that $|T_n(x)| = 1$ for $n + 1$ distinct values of $x$ in $[-1, 1]$. Specify these values.
Property of minimum norm:

From, the previous study of Chebyshev polynomials we have

\[ T_n(x) = 2^{n-1} \prod_{k=0}^{n-1} (x - r_k) \quad \text{with} \quad r_k = \cos \left( (2k + 1) \frac{\pi}{2n} \right), \quad 0 \leq k \leq n - 1, \]

and

\[ |T_n(x)| = 1 \iff x = m_k = \cos \left( k \frac{\pi}{n} \right), \quad 0 \leq k \leq n, \]

with

\[ T_n(m_k) = \cos(k\pi) = (-1)^k. \]

As already mentioned, the roots \( r_k \) are called the Chebyshev points of order \( n \) relative to the interval \([-1, 1]\).

Proposition 3.12 (property of minimum norm)

Let \( h(x) \) be an \( n \)-degree polynomial with leading term equal to \( 2^{n-1} x^n \).

Assuming that \( h(x) \neq T_n(x) \), we have

\[ \max_{x \in [-1,1]} |h(x)| > \max_{x \in [-1,1]} |T_n(x)| = 1 \]
Proof (of property of minimum norm)

We proceed by contradiction.

- Assume that \( \max_{x \in [-1,1]} |h(x)| \leq 1 \), and consider the polynomial \( \gamma(x) = h(x) - T_n(x) \) which is of degree \( n - 1 \) as the leading terms of \( h(x) \) and \( T_n(x) \) are identical.

We then prove that \( \gamma(x) \) admits \( n \) roots in \([-1,1]\), precisely one root in each interval \([m_{k+1}, mk]\), from which we will deduce the result.

- If \( k \) is an even integer, we have by our assumption:
  
  \[
  \gamma(m_{k+1}) = h(m_{k+1}) - T_n(m_{k+1}) = h(m_{k+1}) - (-1)^{k+1} = h(m_{k+1}) + 1 \geq 0
  \]

  \[
  \gamma(m_k) = h(m_k) - T_n(m_k) = h(m_k) - (-1)^k = h(m_{k+1}) - 1 \leq 0
  \]

The result is symmetric if \( k \) is an odd integer.

Thus, \( \gamma(x) \) admits (at least) one root \( \xi_k \) in each close interval \([m_{k+1}, mk]\), \( 0 \leq k \leq n - 1 \).

- Assume now that this root \( \xi_k \) is at an edge of the interval \([m_{k+1}, mk]\), let say \( m_k \), (with \( k \neq 0 \) and \( k \neq n \)). Then, \( h(m_k) = T_n(m_k) \) and \( m_k \) is an extremum of the polynomial \( h(x) \) and of course of \( T_n(x) \), so that \( \gamma'(m_k) = h'(m_k) - T'_n(m_k) = 0 \). Consequently, the polynomial \( \gamma(x) \) admits a double root in \( \xi_k = m_k \).

The end of the proof consists in a technical counting (with multiplicity) of the distinct roots.
Proposition 3.13 (Chebyshev points on \([-1, 1]\))

The best distribution of \(n + 1\) points on the interval \([-1, 1]\) is the sequence of Chebyshev points of order \(n + 1\) over the interval \([-1, 1]\):

\[
r_k = \cos \left( (2k + 1) \frac{\pi}{2n + 2} \right), \quad 0 \leq k \leq n,
\]

and the minimum norm is

\[
\left\| \Pi_{n+1}(x) \right\| = \left\| \prod_{k=0}^{n} (x - r_k) \right\| = \left\| \frac{1}{2^n} T_{n+1}(x) \right\| = \frac{1}{2^n}.
\]

Proposition 3.14 (Chebyshev points on \([a, b]\))

The best distribution of \(n + 1\) points on the interval \([a, b]\) is the sequence of Chebyshev points of order \(n + 1\) over the interval \([a, b]\):

\[
\hat{r}_k = \frac{a + b}{2} + \frac{b - a}{2} \cos \left( (2k + 1) \frac{\pi}{2n + 2} \right), \quad 0 \leq k \leq n,
\]

and the minimum norm is

\[
\left\| \prod_{k=0}^{n} (x - \hat{r}_k) \right\| = \left( \frac{b - a}{2} \right)^{n+1} \frac{1}{2^n} = 2 \left( \frac{b - a}{4} \right)^{n+1}.
\]
Chebyshev points — Main result

Proof (Chebyshev points on \([-1, 1]\) and \([a, b]\))

- By the property of minimum norm, the optimal solution on \([-1, 1]\) is
  \[
  \Pi_{n+1}(x) = \frac{1}{2^n} T_{n+1}(x) = \prod_{k=0}^{n} (x - r_k) \quad \text{and} \quad ||\Pi_{n+1}|| = \frac{1}{2^n}
  \]

- The solution over a general interval \([a, b]\) is derived from the affine transformation
  \[
  [-1, 1] \quad \rightarrow \quad [a, b] \quad \text{with} \quad \varphi(x) = \frac{a + b}{2} + \frac{b - a}{2} x.
  \]

Given a set of \(n + 1\) distinct values \(u_i\) in the interval \([a, b]\), associated with \(n + 1\) distinct values \(x_i = \varphi^{-1}(u_i)\) in \([-1, 1]\), we have

\[
\prod_{i=0}^{n} (u - u_i) = \prod_{i=0}^{n} (\varphi(x) - \varphi(x_i)) = \prod_{i=0}^{n} \left( \frac{b - a}{2} (x - x_i) \right) = \left( \frac{b - a}{2} \right)^{n+1} \prod_{i=0}^{n} (x - x_i)
\]

which concludes the proof.
Proposition 3.15 (Alternation/equioscillation property)

The optimal solution \( \Pi_{n+1}(x) = \frac{1}{2^n} T_{n+1}(x) = (x - r_0)(x - r_1) \cdots (x - r_n) \) is characterized by the fact that the norm \( \| \Pi_{n+1} \| \) is reached at exactly \( n + 2 \) distinct points in the interval \([-1, 1]\): once between each point \( r_k \) and \( r_{k+1} \) and once at each edge of the interval.

Convergence — Objective

- **Error:**

\[ E_n = \max_{x \in [a,b]} |P_n(x,f) - f(x)| \]

\[ a = \min x_i, \quad b = \max x_i \]

- **Choice of interpolation data:**

\[ n \in \mathbb{N}, \quad \min_{x_i \in [a,b]} (E_n) \leq \frac{||f^{(n+1)}||}{(n+1)!} \min_{x_i \in [a,b]} ||\Pi_{n+1}|| \]

Optimal distribution \(\rightarrow\) Chebyshev points

- **Convergence:**

\[ \lim_{n \to \infty} E_n = \ldots \]
Objective: Given a function \( f \in C^p[a, b] \) (\( p \geq 0 \)), and considering for each \( n \in \mathbb{N}^* \) a sequence of \( n + 1 \) distinct points \( x_{n,i} \):

\[
a \leq x_{n,0} < x_{n,1} < \cdots < x_{n,n} \leq b
\]

and the associated interpolating polynomial \( P_n(.,f) \) of \( f \) at these \( n + 1 \) points \( x_{n,i} \), we consider the question of the convergence of the sequence of the interpolating polynomials \( P_n(.,f) \to f \) when \( n \) tends to \(+\infty\)

- Convergence may be understood pointwise or uniform
- Convergence can only be achieved on a subset of the interval \([a, b]\)
- We essentially consider here the following two distributions of interpolation data:
  - Chebyshev distribution \( \rightarrow \) Chebyshev interpolation
  - \( \rightarrow \) Chebyshev interpolating polynomial
  - Uniform distribution \( \rightarrow \) Uniform interpolation
  - \( \rightarrow \) Uniform interpolating polynomial

Runge’s phenomenon

Runge’s phenomenon\(^2\) is a problem of oscillations that occurs (for certain functions) with \textit{uniform interpolation} when the degree increases.

Carl Runge noticed the behaviour of polynomial interpolation in 1901 when studying the approximation of certain rational functions by polynomials. This discovery was surprising at this time because of the Weierstrass theorem (see chapter on Approximation) it was thought that going to higher degrees would improve accuracy.

Precisely, the classical example of this Runge phenomenon is provided by the rational function

\[
f_R(x) = \frac{1}{1 + 25x^2}
\]

defined on the interval \([-1, 1]\), that we interpolate at \textit{uniformly} distributed data points in the interval \([-1, 1]\).

Convergence — Runge’s phenomenon (3)

Runge’s phenomenon

Runge’s phenomenon is a problem of oscillations that occurs (for certain functions) with uniform interpolation when the degree increases.

Brief analysis of this phenomenon:

Considering more generally the function $f_\alpha(x) = \frac{1}{\alpha^2 + x^2}$, $x \in [-1, 1]$ where $\alpha > 0$ is a parameter, and denoting by $P_n(x, f_\alpha)$ its uniform interpolating polynomial of degree $n$, we have the following result.

$\alpha > \alpha_0 \simeq 0.526$: the sequence $P_n(x, f_\alpha)$ converges uniformly to $f_\alpha$ on $[-1, 1]$.

$\alpha < \alpha_0$: the sequence $P_n(x, f_\alpha)$ converges uniformly to $f_\alpha$ on any close interval contained in the open interval $]-\bar{x}, \bar{x}[ \text{ and diverges in } [-1, -\bar{x}[ \cup ]\bar{x}, 1]$, where $\bar{x}$ is solution of the following equation

$$(1 + x)\frac{1+x}{2} (1 - x)\frac{1-x}{2} = \sqrt{1 + \alpha^2} \exp \left( \alpha \arctan \left( \frac{1}{\alpha} \right) \right)$$

The classical function $f_R$ studied by C. Runge corresponds to parameter $\alpha = 1/5 < \alpha_0$, which allows to compute the value $\bar{x} \simeq 0.7266768$. The interval $(-\bar{x}, \bar{x})$ has been plotted in bold green in the previous figures.

Proposition 3.16 (strong convergence)

Let \( f \in C^\infty [a, b] \), such that

\[
\exists M \in \mathbb{R}^+, \quad \forall k \in \mathbb{N}, \quad \| f^{(k)} \| = \max_{x \in [a,b]} | f^{(k)}(x) | \leq M.
\]

Then, for any sequence \((x_n,i)\) of interpolation points in \([a, b]\), the sequence of the associated interpolating polynomials \( P_n(\cdot, f) \) converges uniformly to \( f \) on the interval \([a, b]\) when \( n \) tends to \(+\infty\).

Proof

By inequality (4) given in section “Error bounds in Lagrange interpolation”, we have for any \( n \in \mathbb{N}^* \):

\[
\| f - P_n(\cdot, f) \| = \max_{x \in [a,b]} | f(x) - P_n(x,f) | \leq \frac{\| \Pi_{n+1} \|}{(n + 1)!} \| f^{(n+1)} \| \leq \frac{(b - a)^{n+1}}{(n + 1)!} M
\]

which gives the result.
Convergence — Strong convergence

Example 1

Uniform interpolation on the interval \([a, b]\)

\[ f(x) = 10 \cos(x/2), \quad x \in [-10, 10] \]

\[ \| f^{(k)} \| \leq 10, \quad \forall k \in \mathbb{N} \]
**Example 1**

*Uniform interpolation on the interval \([a, b]\)*

\[
f(x) = 10 \cos\left(\frac{x}{2}\right), \quad x \in [-10, 10]
\]

\[
\|f^{(k)}\| \leq 10, \quad \forall k \in \mathbb{N}
\]
Example 1

Uniform interpolation on the interval $[a, b]$:

$$ f(x) = 10 \cos(x/2), \quad x \in [-10, 10] $$

$$ \|f^{(k)}\| \leq 10, \quad \forall k \in \mathbb{N} $$
Uniform interpolation on the interval $[a, b]$
Example 2

Uniform interpolation on a sub-interval of \([a, b]\)

\[ f(x) = \cos(x), \quad x \in [-2\pi, 3\pi] \]

\[ ||f^{(k)}|| \leq 1, \quad \forall k \in \mathbb{N} \]

Uniform data points are sampled in the sub-interval \([0, \pi]\) for degrees 4, 8, 12, 16
**Convergence — Strong convergence**

**Example 2**

*Uniform interpolation on a sub-interval of \([a, b]\)*

\[
\begin{align*}
f(x) &= \cos(x), & x \in [-2\pi, 3\pi] \\
||f^{(k)}|| &\leq 1, \forall k \in \mathbb{N}
\end{align*}
\]

*Uniform data points are sampled in the sub-interval \([0, \pi]\) for degrees 4, 8, 12, 16*
Example 2

Uniform interpolation on a sub-interval of \([a, b]\)

\[ f(x) = \cos(x), \quad x \in [-2\pi, 3\pi] \]
\[ ||f^{(k)}|| \leq 1, \quad \forall k \in \mathbb{N} \]

Uniform data points are sampled in the sub-interval \([0, \pi]\) for degrees 4, 8, 12, 16
Example 2

Uniform interpolation on a sub-interval of \([a, b]\)

\[ f(x) = \cos(x), \quad x \in [-2\pi, 3\pi] \]

\[ \|f^{(k)}\| \leq 1, \quad \forall k \in \mathbb{N} \]

Uniform data points are sampled in the sub-interval \([0, \pi]\) for degrees 4, 8, 12, 16
Example 2

Uniform interpolation on a sub-interval of \([a, b]\)

Connection with Taylor expansion

\(f(x) = \cos(x), \ x \in [-2\pi, 3\pi]\)
Example 3

Uniform interpolation on a sub-interval of \([a, b]\)

Runge function \(f_R(x) = \frac{1}{1 + 25x^2}, \quad x \in [-1, 1]\)

Uniform data points are sampled in the sub-interval \([-0.08, 0.08]\)

for degrees 4, 8, 12, 16, 20
Example 3

Uniform interpolation on a sub-interval of $[a, b]$

Runge function $f_R(x) = \frac{1}{1 + 25x^2}$, $x \in [-1, 1]$

Uniform data points are sampled in the sub-interval $[-0.08, 0.08]$ for degrees 4, 8, 12, 16, 20
Example 3

Uniform interpolation on a sub-interval of $[a, b]$

Runge function $f_R(x) = \frac{1}{1+25x^2}$, $x \in [-1, 1]$

Uniform data points are sampled in the sub-interval $[-0.08, 0.08]$ for degrees 4, 8, 12, 16, 20
Example 3

Uniform interpolation on a sub-interval of \([a, b]\)

Runge function

\[ f_R(x) = \frac{1}{1 + 25x^2}, \quad x \in [-1, 1] \]

Uniform data points are sampled in the sub-interval \([-0.08, 0.08]\) for degrees 4, 8, 12, 16, 20
Example 3

Uniform interpolation on a sub-interval of $[a, b]$

Runge function $f_R(x) = \frac{1}{1 + 25x^2}, \quad x \in [-1, 1]$

Uniform data points are sampled in the sub-interval $[-0.08, 0.08]$ for degrees $4, 8, 12, 16, 20$
Example 3

Uniform interpolation on a sub-interval of $[a, b]$

Runge function $f_R(x) = \frac{1}{1+25x^2}$, $x \in [-1, 1]$

Uniform data points are sampled in the sub-interval $[-0.08, 0.08]$ for degrees 4, 8, 12, 16, 20
Example 3

Uniform interpolation on a sub-interval of \([a, b]\)

Connection with Taylor expansion

Radius of convergence \( R = 0.2 \)

Runge function \( f_R(x) = \frac{1}{1 + 25x^2}, \quad x \in [-1, 1] \)
Proposition 3.17 (K-Lipschitz functions)

Assume that the function $f$ is $K$-Lipschitz, which means that for all $x, y \in [a, b]$, we have $|f(x) - f(y)| \leq K |x - y|$. Then, the sequence of Chebyshev interpolating polynomials converges uniformly to $f$ on $[a, b]$.

**Example:** we consider the absolute function. Since $||x| - |y|| \leq |x - y|$ for all $x, y \in \mathbb{R}$, we deduce that the absolute function is 1-Lipschitz, so that the previous proposition applies.

Notice the behaviour of the interpolating polynomials at the non differentiable point.
Convergence — K-Lipschitz functions

Proposition 3.17 (K-Lipschitz functions)

Assume that the function $f$ is K-Lipschitz, which means that for all $x, y \in [a, b]$, we have $|f(x) - f(y)| \leq K |x - y|$. Then, the sequence of Chebyshev interpolating polynomials converges uniformly to $f$ on $[a, b]$.

Example: we consider the absolute function. Since $|x| - |y| \leq |x - y|$ for all $x, y \in \mathbb{R}$, we deduce that the absolute function is 1-Lipschitz, so that the previous proposition applies.

Notice the behaviour of the interpolating polynomials at the non differentiable point.
Convergence — Theoretical results...

The following results provide an interesting insight into the interpolation and convergence process, but their practical relevance is limited.

**Proposition 3.18 (Marcinkiewicz)**

For any function \( f \in C[a, b] \), there exists a triangular sequence of points \( x_{n,i} \in [a, b] \), \( n = 0, 1, 2, \ldots \) and \( 0 \leq i \leq n \), so that the associated sequence of interpolating polynomials \( P_n(x,f) \) converges uniformly to \( f \) on \([a, b]\).

In contrast, we have the following theorem.

**Proposition 3.19 (Faber & Bernstein)**

For any triangular sequence of points \( x_{n,i} \in [a, b] \), \( n = 0, 1, 2, \ldots \) and \( 0 \leq i \leq n \), there exists a continuous function \( f \in C[a, b] \) so that the associated sequence of interpolating polynomials \( P_n(x,f) \) does not converge uniformly to \( f \) on \([a, b]\).
Proof (of Marcinkiewicz proposition)

The proof is a direct consequence of the Weierstrass approximation theorem which states that there exists a sequence of polynomials $p_n(x)$ of best approximation (see chapter related to approximation) which converges uniformly to $f$.

Then, due to the equioscillation property, the graph of each polynomial of best approximation $p_n(x)$ intersects the graph of $f$ at $n + 1$ distinct values $x_{n,i}$.

Consequently, by uniqueness, the interpolating polynomial $P_n(x, f)$ at these values coincides with $p_n(x)$, which gives the result.

Some quotes... (from Nick Trefethen)

Faber (1914) : “No matter what the grids are, polynomial interpolants diverge for some $f$”
Stewart (1996), p 153 : “Unfortunately, there are functions for which interpolation at the Chebyshev points fails to converge.”

Polynomial interpolation in Chebyshev points is equivalent to trigonometric interpolation of periodic functions in equispaced points, whose convergence nobody worries about.
Parlett (2010), SIAM Review book review : “You do not want to meet a polynomial of degree 1000 on a dark night.”
Forsythe, Malcolm & Moler (1977), p 68 : “Polynomial interpolation has drawbacks in addition to those of global convergence. The determination and evaluation of interpolating polynomials of high degree can be too time-consuming for certain applications. Polynomials of high degree can also lead to difficult problems associated with roundoff error.”
Froberg (1985), p 234 : “Although Lagrangian interpolation is sometimes useful in theoretical investigations, it is rarely used in practical computations.”
Parametric interpolation —

1. Background on interpolation
2. Polynomial Lagrange interpolation
3. Implementation
4. Monomial form
5. Lagrange form
6. Newton form
7. Error bounds in Lagrange interpolation
8. Chebyshev points
9. Convergence
10. Parametric interpolation
Objective

Given a sequence of points $M_i = (x_i, y_i)$, $0 \leq i \leq n$, we look for a polynomial parametric curve of degree $n$ which interpolates these data points, that is which goes through each point $(x_i, y_i)$ for some parameter $t_i$.

The main question consists in the choice of the interpolation parameters $t_i$, which are also called the interpolation nodes or simply the nodes.

Essentially, we consider three choices for the interpolation parameters.

- The first one is the uniform parametrization: parameters $t_i$ are evenly spaced in the parameter domain.
- The second one is the Chebyshev parametrization.
- The last one is the chordal parametrization: parameters are chosen in such a way that distances between successive parameters $t_i$ are proportional to the distances between associate successive data points $M_i$. The chordal parametrization is more reliable and faithful with respect to the geometry of the initial data.
Parametric interpolation — Problem statement

**Modelling**

Precisely, we look for a \( n \)-degree polynomial parametric curve

\[
[a, b] \in \mathbb{R} \quad \mapsto \quad \mathbb{R}^2 \\
\begin{align*}
m : & \quad t \quad \mapsto \quad m(t) = \left(\begin{array}{c} m_x(t) \\ m_y(t) \end{array}\right) 
\end{align*}
\]

such that

\[
m(t_i) = M_i \iff \left\{ \begin{array}{l} m_x(t_i) = x_i \\ m_y(t_i) = y_i \end{array} \right. , \quad 0 \leq i \leq n
\]

with a sequence of interpolation nodes \( a \leq t_0 < t_1 < \cdots < t_n \leq b \), and where \( m_x(t) \) and \( m_y(t) \) are polynomials of degree \( n \). As a result, we are reduced to solving two separate polynomial interpolation problems.

Considering the parameters domain \([a, b] = [0, 1]\) (that does not affect the method), the choices for the interpolation nodes \( t_i \) are the following.

- **Uniform parameterization**: \( t_{i+1} - t_i = 1/n \)
- **Chebyshev parameterization**: \( \hat{t}_i = \frac{a + b}{2} + \frac{b - a}{2} \cos \left( \frac{2i + 1}{2n + 2} \pi \right) \)
- **Chordal parameterization**: \( t_{i+1} - t_i = \frac{d_i}{\sum_{k=0}^{n-1} d_k} \) with \( d_k = \text{dist}(M_k, M_{k+1}) \)
Parametric interpolation — Examples
Parametric interpolation of the Lissajous curve: \( t \mapsto (x = \sin(2t), y = \sin(3t)), \ t \in [0, 2\pi] \).

We first choose \( n + 1 \) points on the curve through a uniform sampling in the parameter domain. We then interpolate this sampling by polynomial parametric curves of different degrees with the same (uniform) parameters. As the sine function is analytic, the convergence is insured.
